13 | Advanced Metrics

Ivan Corneillet

Data Scientist

Learning Objectives

After this lesson, you should be able to:

- Evaluate a binary classification model using advanced metrics such as confusion matrix, ROC, and AUC curves
- Explain the trade-offs between false positives and false negatives

Here's what's happening today:

- Confusion Matrix
- True Positives and False Positives
- ROC and AUC

Accuracy and Misclassification Rate

- Accuracy is only one of several metrics used when solving for a classification problem
 - E.g., if we know a prediction is 75% accurate, accuracy doesn't provide any insight into why the 25% was wrong. Was it wrong *equally* across all class labels? Did it just guess one class label for all predictions and 25% of the data was just the other label?
- It's important to look at other metrics to fully understand the problem

Accuracy

How many observations that we predicted were correct? This is a value we'd want to increase (like R^2)

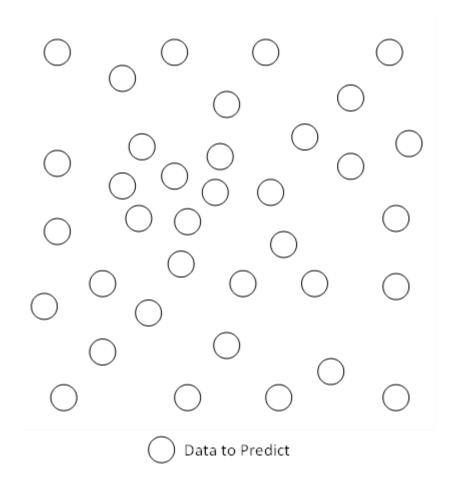

Misclassification rate

- Directly opposite of accuracy
- Of all the observations we predicted, how many were incorrect? This is a value we'd want to decrease (like the mean squared error)

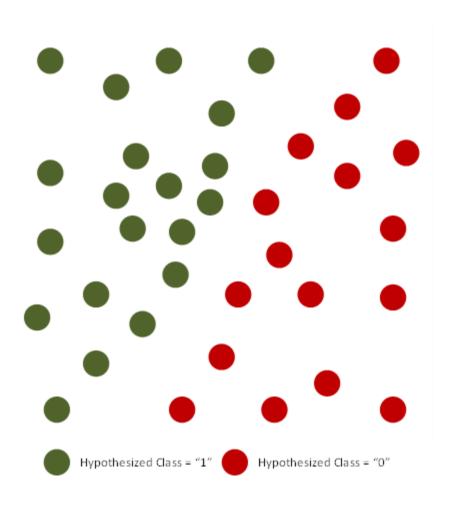

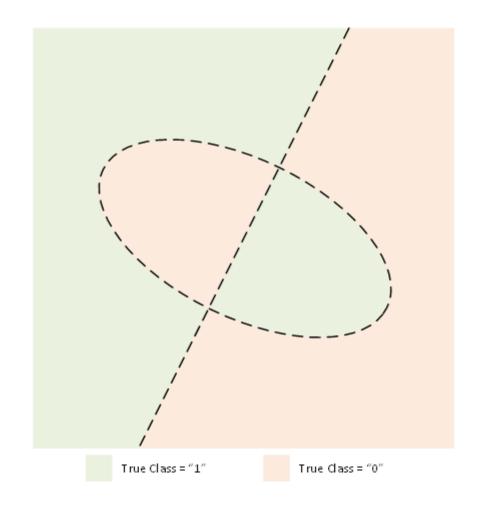

Confusion Matrix

Stepping back | Let's say we want to classify this data:

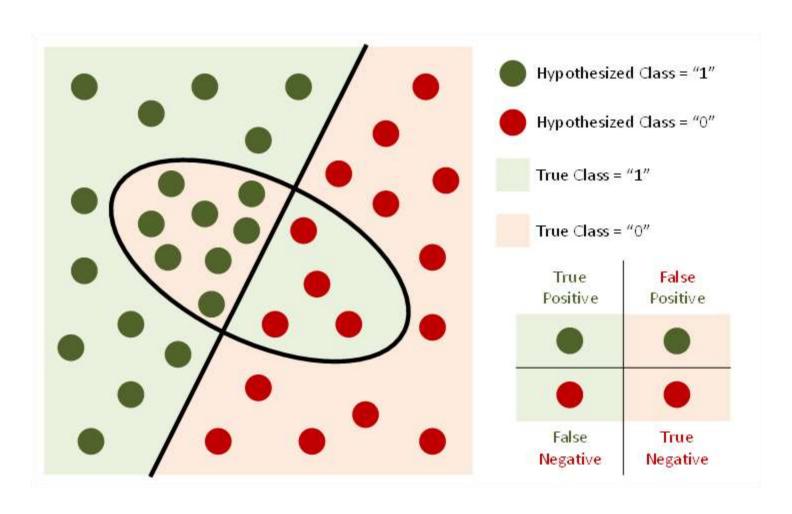

Hypothesized and true classes don't necessarily match

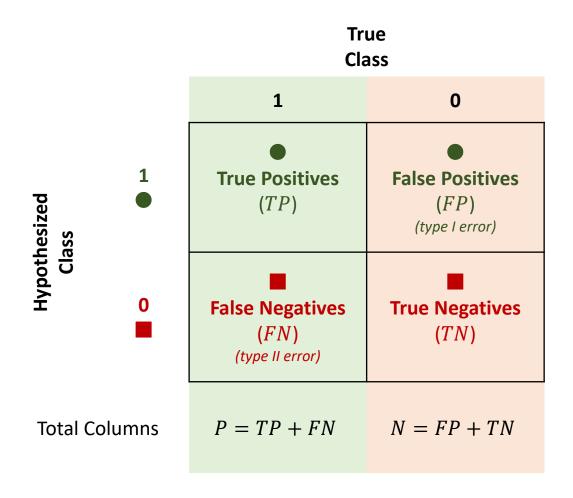

We can rearrange these 4 possibilities into a 2x2 table

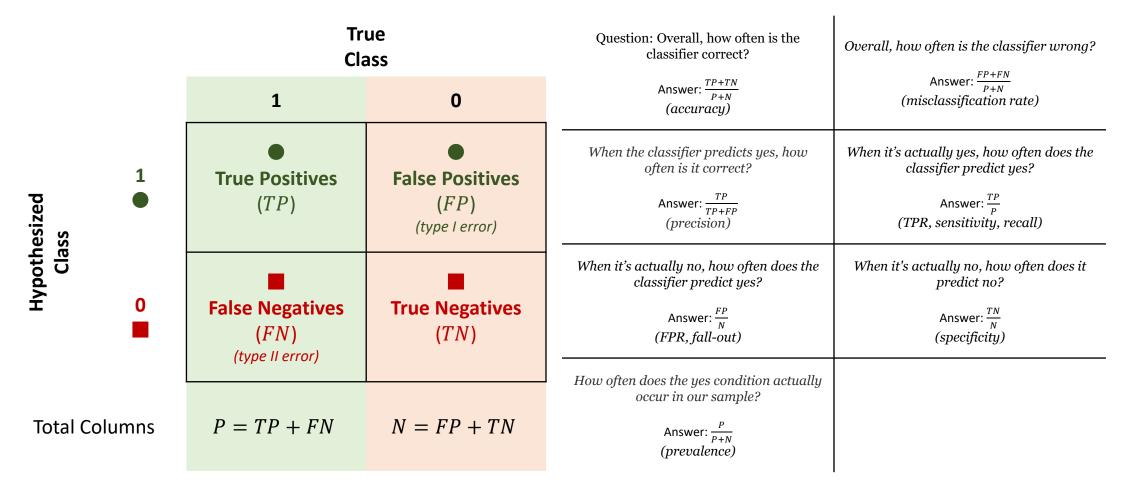

Confusion Matrix (a.k.a., Contingency Table or Error Matrix)

- A confusion matrix is a specific table layout that allows visualization of the performance of a supervised learning algorithm
- Each row of the matrix represents the instances in a predicted class while each column represents the instances in an actual class
- The name stems from the fact that it makes it easy to see if the system is confusing two classes (i.e., commonly mislabeling one as another)

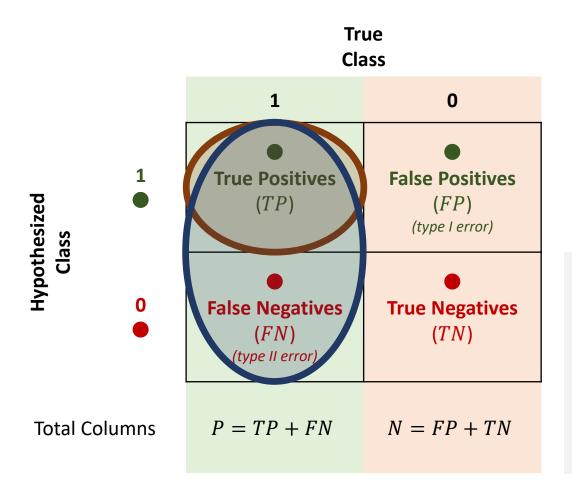

Interpreting the Confusion Matrix

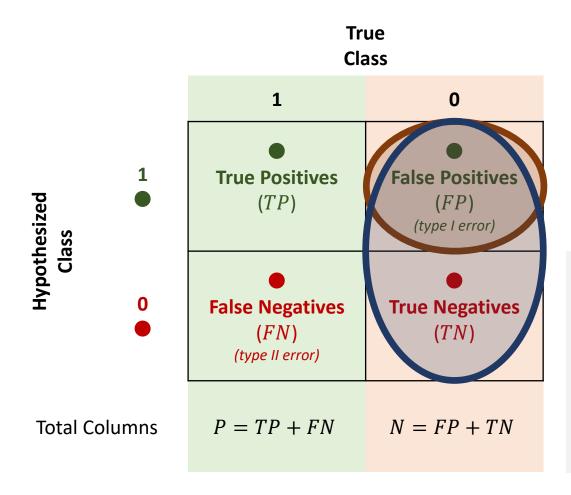

True and False Positive Rates

True Positive Rate, $TPR = \frac{TP}{P}$

- When it's actually yes, how often does the classifier predict yes?
- A.k.a., "Sensitivity"
- E.g., given a medical exam that tests for cancer, how often does it correctly identify patients with cancer?
- Likewise, this can be inverted: how often does a test *correctly* identify patients without cancer

False Positive Rate, $FPR = \frac{FP}{N}$

- When it's actually no, how often does the classifier predict yes?
- A.k.a., "Fall-out"
- E.g., given a medical exam that tests for cancer, how often does it trigger a "false alarm" by saying a patient has cancer when they actually don't?
- Likewise, this can be also inverted: how often does a test
 incorrectly identify patients as being cancer-free when they
 might actually have cancer!

True Positive and False Positive Rates

 We can split up the accuracy of each label by using true positive and false positive rates. Using them, we can get a much clearer picture of where predictions begin to fall apart

 A good classifier would have a true positive rate approaching 1, and a false positive rate approaching o. In a binary problem (say, predicting if someone smokes or not), it would accurately predict all of the smokers as smokers, and not accidentally predict any of the non-smokers as smokers

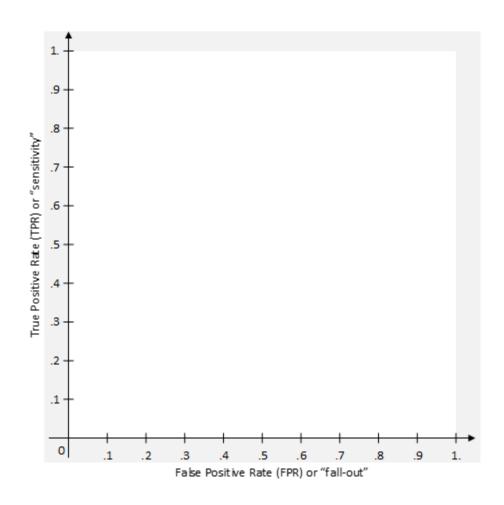

ROC and AUC

ROC (receiver operating characteristic or relative operating characteristic) and AUC (Area Under the Curve)

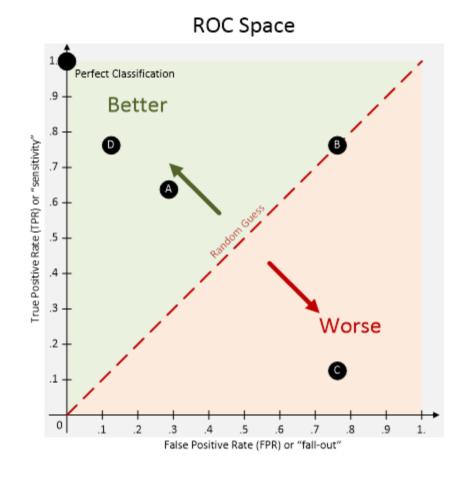

ROC (receiver operating characteristic) curve (a.k.a., relative operating characteristic curve)

- An ROC curve plots the true positive rate (TPR) (or "sensitivity") against the false positive rate (FPR) (or "fallout") at various threshold settings to illustrate the performance of a binary classifier system
- The ROC curve is thus the sensitivity as a function of fall-out

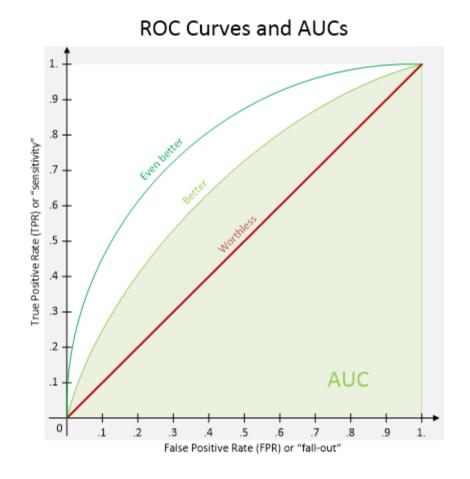

ROC curves demonstrate several things:

- It shows the tradeoff between sensitivity and fall-out (any increase in sensitivity will be accompanied by an increase in fallout)
 - The closer the **points** are in the left-hand border and then the top border of the ROC space, the more accurate the classifier is
 - The closer the **points** come to the 45-degree diagonal of the ROC space, the less accurate the classifier is

ROC curves demonstrate several things: (cont.)

- The AUC (Area Under the Curve) is a measure of classifier accuracy
 - The closer the curve follows the lefthand border and then the top border of the ROC space, the more accurate the classifier is
 - The closer the **curve** comes to the 45degree diagonal of the ROC space, the less accurate the classifier is

Plotting an ROC curve

- lacktriangle Discard \hat{c} (hypothesized class) and whether it is a true/false positive/negative
- Order the trained sample by their decreasing hypothesized probabilities \hat{p} (from more confident to have a '1' down to less confident to have a '1')
- lacktriangle Discard the original ranking from the dataset as well as \hat{p}
- **4** Start at (0, 0)
- **6** For each training sample in the sorted order
 - If c = 1, move up by $\frac{1}{P}$
 - If c = 0, move up by $\frac{1}{N}$
- 6 If not already at (1, 1), go all the way to the right, then up all the way to (1, 1)

Let's plot the ROC for the following trained binary classifier

#	\hat{p}	ĉ	С	True/False Positive/Negative
1	.44	0	1	FN
2	.29	0	0	TN
3	.98	1	1	TP
4	.69	1	0	FP
5	.07	0	1	FN

lacktriangle Discard \hat{c} (hypothesized class) and whether it is a true/false positive/negative

#	\hat{p}	ĉ	С	True/False Positive/Negative
1	.44	0	1	FN
2	.29	0	0	ŦN
3	.98	1	1	TP
4	.69	1	0	FP
5	.07	0	1	FN

lacktriangle Discard \hat{c} (hypothesized class) and whether it is a true/false positive/negative (cont.)

#	\hat{p}	С
1	.44	1
2	.29	0
3	.98	1
4	.69	0
5	.07	1

2 Order the trained sample by their decreasing hypothesized probabilities \hat{p} (from more confident to have a '1' down to less confident to have a '1')

_	#' (ranking by decreasing probabilities)	# (ranking from dataset)	\hat{p}	С
	1	3	.98	1
_	2	4	.69	0
	3	1	.44	1
	4	2	.29	0
_	5	5	.07	1

$oldsymbol{3}$ Discard the original ranking from the dataset as well as \hat{p}

#' (ranking by decreasing probabilities)	# (ranking from dataset)	p	С
1	3	.98	1
2	4	.69	0
3	1	. 44	1
4	2	.29	0
5	5	.07	1

$oldsymbol{\mathfrak{G}}$ Discard the original ranking from the dataset as well as \hat{p} (cont.)

#' (ranking by decreasing probabilities)	С
1	1
2	0
3	1
4	0
5	1

Let's plot the ROC/AUC for the following trained binary classifier (cont.)

#' (ranking by decreasing probabilities)	С
1	1
2	0
3	1
4	0
5	1

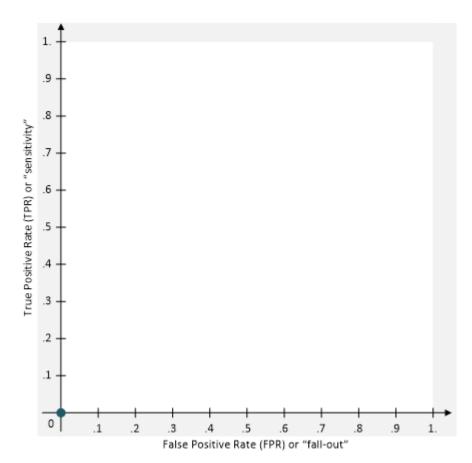

$$P = 3 \rightarrow \frac{1}{P} = \frac{1}{3}$$

$$N = 2 \rightarrow 1/N = 1/2$$

Start at (0, 0)

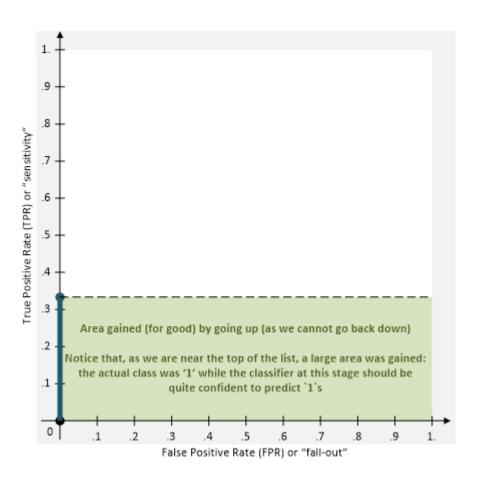

#' (ranking by decreasing probabilities)	С
1	1
2	0
3	1
4	0
5	1

6 Because c = 1, move up by $\frac{1}{P} = \frac{1}{3}$

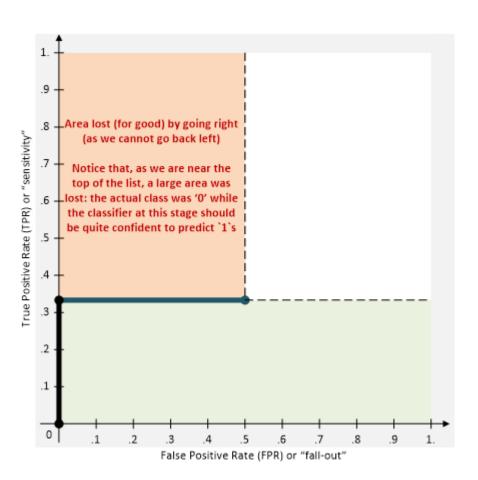

#' (ranking by decreasing probabilities)	С
1	1
2	0
3	1
4	0
5	1

6 Because c = 0, move right by $\frac{1}{N} = \frac{1}{2}$

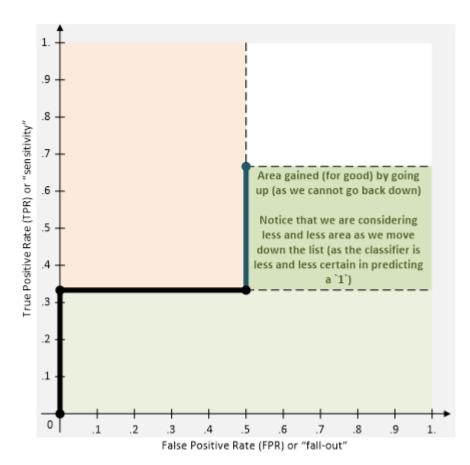

#' (ranking by decreasing probabilities)	С
1	1
2	0
3	1
4	0

6 Because c = 1, move up by $\frac{1}{P} = \frac{1}{3}$

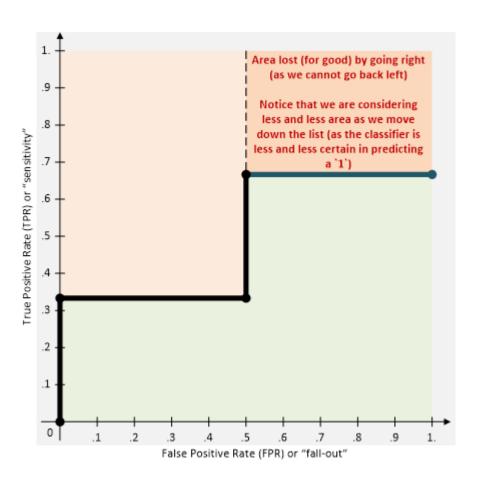

#' (ranking by decreasing probabilities)	С
1	1
2	0
3	1
4	0

6 Because c = 0, move left by $\frac{1}{N} = \frac{1}{2}$

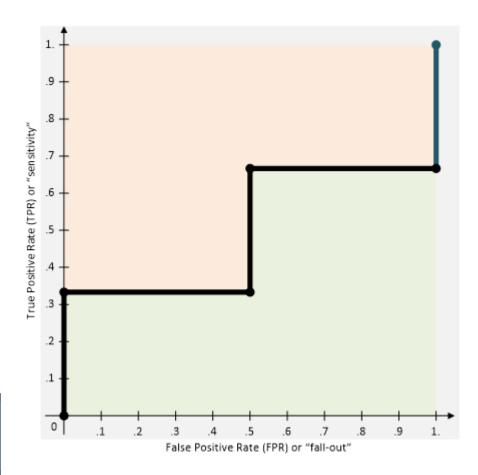

#' (ranking by decreasing probabilities)	С
1	1
2	0
3	1
4	0
5	1

6 Because c = 1, move up by $\frac{1}{P} = \frac{1}{3}$

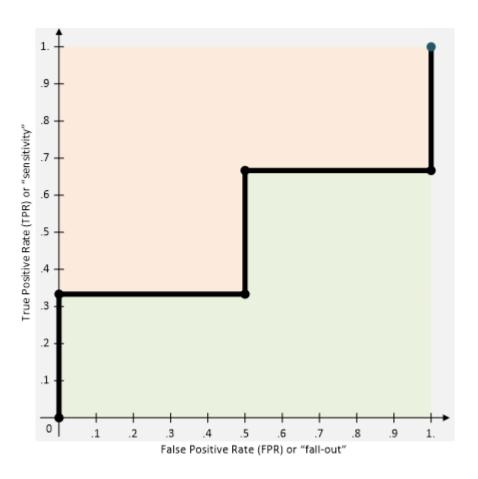

#' (ranking by decreasing probabilities)	С
1	1
2	0
3	1
4	0
5	1

If not already at (1, 1), go all the way to the right, then up all the way to (1, 1)

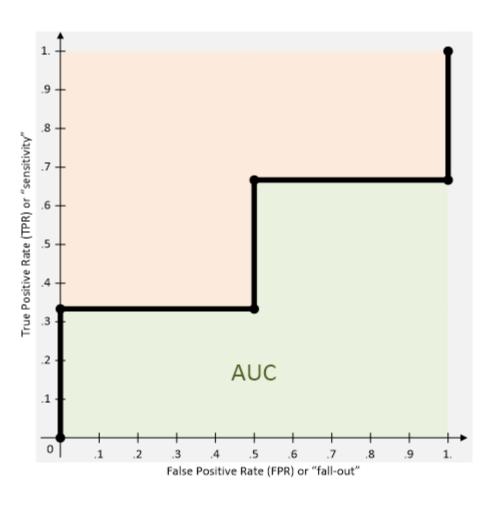

#' (ranking by decreasing probabilities)	С
1	1
2	0
3	1
4	0
5	1

Let's plot the ROC/AUC for the following trained binary classifier (cont.)

Plotting an ROC curve (cont.)

Notes

- We don't rely on a threshold (e.g., .5) for plotting ROC curves. Indeed, moving up or right is independent of \hat{p} (we discarded it in step \mathbf{G}) and only relies on a decreasing ranking of \hat{p} and then c
- As a matter of fact, you can use ROC curves to select the best threshold but we won't address it here
